

## Problem Set #3

MACS 40200, Dr. Evans

Due Tuesday, Jan. 24 at 12:00pm

1. **MLE estimation of simple macroeconomic model (10 points).** You can observe time series data in an economy for the following variables:  $(c_t, k_t, w_t, r_t)$ . Data on  $(c_t, k_t, w_t, r_t)$  can be loaded from the file `MacroSeries.txt`. This file is a comma separated text file with no labels. The variables are ordered as  $(c_t, k_t, w_t, r_t)$ . These data have 100 periods, which are quarterly (25 years). Suppose you think that the data are generated by a process similar to the [Brock and Mirman \(1972\)](#). A simplified set of characterizing equations of the Brock and Mirman model are the following.

$$(c_t)^{-1} - \beta E[r_{t+1}(c_{t+1})^{-1}] = 0 \quad (1)$$

$$c_t + k_{t+1} - w_t - r_t k_t = 0 \quad (2)$$

$$w_t - (1 - \alpha)e^{z_t}(k_t)^\alpha = 0 \quad (3)$$

$$r_t - \alpha e^{z_t}(k_t)^{\alpha-1} = 0 \quad (4)$$

$$z_t = \rho z_{t-1} + (1 - \rho)\mu + \varepsilon_t \quad (5)$$

where  $\varepsilon_t \sim N(0, \sigma^2)$

The variable  $c_t$  is aggregate consumption in period  $t$ ,  $k_{t+1}$  is total household savings and investment in period  $t$  for which they receive a return in the next period (this model assumes full depreciation of capital). The wage per unit of labor in period  $t$  is  $w_t$  and the interest rate or rate of return on investment is  $r_t$ . Total factor productivity is  $z_t$ , which follows an AR(1) process given in (5). The rest of the symbols in the equations are parameters that must be estimated  $(\alpha, \beta, \rho, \mu, \sigma)$ . The constraints on these parameters are the following.

$$\alpha, \beta \in (0, 1), \quad \mu, \sigma > 0, \quad \rho \in (-1, 1)$$

Assume that the first observation in the data file variables is  $t = 1$ . Let  $k_1$  be the first observation in the data file for the variable  $k_t$ . Assume that  $z_0 = \mu$  so that  $z_1 = \mu$ . Assume that the discount factor is known to be  $\beta = 0.99$ .

- (a) (4 points) Use the data  $(w_t, k_t)$  and equations (3) and (5) to estimate the four parameters  $(\alpha, \rho, \mu, \sigma)$  by maximum likelihood. Given a guess for the parameters  $(\alpha, \rho, \mu, \sigma)$ , you can use the two variables from the data  $(w_t, k_t)$  and (3) to back out a series for  $z_t$ . You can then use equation (5) to compute the probability of each  $z_t \sim N(\rho z_{t-1} + (1 - \rho)\mu, \sigma^2)$ . The maximum likelihood estimate  $(\hat{\alpha}, \hat{\rho}, \hat{\mu}, \hat{\sigma})$  maximizes the likelihood function of that normal distribution of  $z_t$ 's. Report your estimates and the inverse hessian variance-covariance matrix of your estimates.

- (b) (4 points) Now we will estimate the parameters another way. Use the data  $(r_t, k_t)$  and equations (4) and (5) to estimate the four parameters  $(\alpha, \rho, \mu, \sigma)$  by maximum likelihood. Given a guess for the parameters  $(\alpha, \rho, \mu, \sigma)$ , you can use the two variables from the data  $(r_t, k_t)$  and (4) to back out a series for  $z_t$ . You can then use equation (5) to compute the probability of each  $z_t \sim N(\rho z_{t-1} + (1 - \rho)\mu, \sigma^2)$ . The maximum likelihood estimate  $(\hat{\alpha}, \hat{\rho}, \hat{\mu}, \hat{\sigma})$  maximizes the likelihood function of that normal distribution of  $z_t$ 's. Report your estimates and the inverse hessian variance-covariance matrix of your estimates.
- (c) (2 points) According to your estimates from part (a), if investment/savings in the current period is  $k_t = 7,500,000$  and the productivity shock in the previous period was  $z_{t-1} = 10$ , what is the probability that the interest rate this period will be greater than  $r_t = 1$ . That is, solve for  $Pr(r_t > 1 | \hat{\theta}, k_t, z_{t-1})$ . [HINT: Use equation (4) to solve for the  $z_t = z^*$  such that  $r_t = 1$ . Then use (5) to solve for the probability that  $z_t > z^*$ .]
